ABSTRACT

DB2 for Linux, UNIX, and Windows Version 9.1 introduces the Self-Tuning Memory Manager (STMM), which provides adaptive self tuning of both database memory heaps and cumulative database memory allocation. This technology provides state-of-the-art memory tuning combining control theory, runtime simulation modeling, cost-benefit analysis, and operating system resource analysis. In particular, the novel use of cost-benefit analysis and control theory techniques makes STMM a breakthrough technology in database memory management. The cost-benefit analysis allows STMM to tune memory between radically different memory consumers such as compiled statement cache, sort, and buffer pools. These methods allow for the fast convergence of memory settings while also providing stability in the presence of system noise. The tuning model has been found in numerous experiments to tune memory allocation as well as expert human administrators, including OLTP, DSS, and mixed environments. We believe this is the first known use of cost-benefit analysis and control theory in database memory tuning across heterogeneous memory consumers.

be relieved of the need to invest time in understanding how the database uses memory before tuning can begin.

2. Uncertain memory requirements for a given workload – In some cases, even experienced DBAs can find it difficult to tune a database's memory because the workload characteristics are unknown. With the introduction of this new feature, the system will now be able to continuously monitor database memory usage and tune when necessary to optimize performance based on the workload characteristics. As a result, the user will require no knowledge of their workload for the memory to be tuned well.

3. Changing workload behavior – For many industrial workloads, no single memory configuration can provide optimal performance because, at different points in time, the workload can exhibit dramatically different memory demands. If STMM is running and the workload's memory demands shift, the system will recognize the changing needs for memory and adapt the memory allocation accordingly. As a result, the user will rarely (if ever) need to manually change the affected memory configuration parameters to enhance performance.

4. Performance tuning is time-consuming – Tuning a database's

System stability

Is highest performance enough?

Final thoughts

Who’s using?

An engineer or an algorithm.

What’s missing?

Higher-order interaction and feedback.

What’s the goal?

Best robust performance.
